

Networked Influence in a Tabula Rasa Legislature

Co-authorship, Ideological Dynamics, and Political Success
in the Chilean Constitutional Convention (2021–2022)

Aníbal Olivera M. · Jorge Fábrega L.

PhD(c) in Social Complexity Sciences, CICS–UDD, Chile

A natural quasi-experiment

- In an ordinary legislature, today's collaboration network is the sediment of decades: careers, committees, party discipline.
- The Chilean Constitutional Convention (Jul 2021 – Jul 2022) started from **zero relational stock**: a majority of newcomers and independents, 17 reserved indigenous seats, a body that dissolved on delivery.
- Each constitutional initiative required **8–16 sponsors**: signing = forming a visible coalition.
- Each norm needed **2/3 of the floor (103 of 154)**, so being born was cheap, but surviving was expensive.

Chile's Constitutional Convention

The pipeline

What we know about each member

- **Political**: electoral list and bloc (Right / Center-left / Left / Reserved seats / Local lists); district of election.
- **Profile**: age; gender; profession — in particular the *law degree*; education level (none / university / master's / PhD).
- **Prior institutional experience**: had held elective or appointed public office before the Convention (former MPs, mayors, officials) — 35 of 154 members.
- **Ideology**: two-dimensional ideal points from the first month of roll calls — measured *before* the collaboration network existed.

Sources: electoral service records and official biographies, audited against two sources per member.

The seven thematic commissions

	Name (short)	Members	% lawyers	% exper.	Age	Degree	Initiatives	Waves
C1	Political system	25	60	36	42.2	1.44	89	4
C2	Const. principles	18	22	22	45.8	1.28	114	3
C3	Form of the state	30	37	40	45.1	1.43	51	6
C4	Fundamental rights	30	30	13	45.9	1.03	283	5
C5	Environment	19	21	16	44.7	1.26	133	5
C6	Justice systems	17	88	18	42.6	1.65	93	6
C7	Knowledge systems	15	13	0	51.7	1.33	64	8

- Composition varies wildly across commissions — C6 is 88% lawyers, C7 has no politically experienced member.

Ideal-point trajectories by commission membership (thin lines = delegates, thick lines = commission means)

Research questions

- **RQ1 — Formation**: can the co-sponsorship network be predicted from what people *brought with them* (ideology, bloc, district, profile)?
- **RQ2a — Positions**: does network exposure *move* members' ideological positions?
- **RQ2b — Behavior**: does voting *defection* travel along co-sponsorship ties?
- **RQ3a — Texts**: what makes an *article* survive into the draft?
- **RQ3b — Members**: does the *context* an initiative is born into matter for its authors' success?

RQ1 — Formation

Could we predict the network?

Bipartite ERGM

- Unit of analysis: the **person** $\times$ **initiative** signature ($y_{ia} = 1$ if member i signed initiative a).

$$\Pr(Y = y) = \frac{\exp(\theta^\top s(y))}{\kappa(\theta)}$$

$$s(y) = \left(\underbrace{\sum_{i,a} y_{ia}}_{\text{edges}}, \underbrace{\sum_a \sum_{i < j} y_{ia} y_{ja} \mathbf{1}\{b_i, b_j\} = \{g, h\}}_{\text{bloc mixing: 15 cells}}, \underbrace{\sum_a \sum_{i < j} y_{ia} y_{ja} \mathbf{1}[x_i = x_j] \mathbf{1}[b_i = b_j = g]}_{\text{profile homophily within bloc } g}, \dots \right)$$

- Variables: per-document ranges of θ_1, θ_2 , age, education; the bloc contingent's own θ_1 range; gwb1degree; gwdsp.
- Seven models, one per commission.
- Estimation: MPLE as a logistic on change statistics; SEs by **initiative bootstrap** (B = 500).

RQ2 — People

Does the network move positions (RQ2a) or behavior (RQ2b)?

RQ2a design: the norms era, and a careful clock

- Everything here uses **only the norms era** (Feb 15 – May 14: content voted under the 2/3 rule) and θ re-estimated with era votes only — a regime-homogeneous thermometer.

$$E_{i,t} = \frac{\sum_{j \neq i} w_{ij,t} \theta_{j,t}}{\sum_{j \neq i} w_{ij,t}} \quad \Delta \theta_{i,t} = \alpha_i + \mu_t + \beta \theta_{i,t-1} + \lambda E_{i,t-1} + \lambda_{innov} \tilde{E}_{i,t+2} + \varepsilon_{it}$$

- α_i : person fixed effects (only within-person variation); μ_t : wave-date fixed effects (common shocks); $\lambda > 0$ = I move toward where my neighborhood was.
- The clock**: positions at $t+1$ are built from votes cast at t . So the lag uses $E_{i,t-1}$ (votes through $t-2$), and the “strictly future” innovation $\tilde{E}_{i,t+2}$ uses $t+2$ — never $t \pm 1$.
- $\tilde{E}_{i,t+2}$: the part of future exposure the past did not contain. If “influence” were really selection — signing with people I’m already moving toward — the future should predict and the lag should die.

The result: basic, common shocks, and the referee's test

	M0 basic	M1 + date FE	M2 + innovation $t+2$
Lagged position $\theta_{i,t-1} (\hat{\beta})$	-0.699***	-0.702***	-0.755***
SE (clustered)	0.027	0.028	0.038
Lagged exposure $\hat{\lambda} (E_{i,t-1})$	+0.021***	+0.020***	+ 0.020** ($p = .003$)
SE (clustered)	0.005	0.005	0.007
Innovation $\hat{\lambda}_{innov} (\tilde{E}_{i,t+2})$	—	—	-0.002 ($p = .91$)
Wave-date fixed effects	no	yes	yes
N (person-waves)	4,065	4,065	2,011
R^2 within	0.366	0.383	0.369

- M0: within each person, movement follows past exposure — closing $\sim 2\%$ of the distance to the neighborhood per wave. M1: not common shocks. M2: the **strictly future innovation predicts nothing** ($p = .91$) — and the lag stands.
- Honest label: an **influence component** that survives every test this panel supports; latent homophily cannot be excluded by design.

Robustness: exposure with decaying memory (norms era)

	$\lambda_w = 0.25$	$\lambda_w = 0.50$	$\lambda_w = 0.75$
Lagged position $\theta_{i,t-1} (\hat{\beta})$	-0.700***	-0.701***	-0.701***
SE (clustered)	0.028	0.028	0.028
Decayed exposure $\hat{\lambda}$	+0.017***	+0.018***	+0.019***
SE (clustered)	0.004	0.004	0.005
Wave-date fixed effects	yes	yes	yes
N (person-waves)	4,065	4,065	4,065
R^2 within	0.383	0.383	0.383

- With memory that discounts the past, the result does not weaken — it sharpens ($p < 10^{-4}$ in all three).
- Contrast with the standard thermometer (mixing agenda regimes): there the same specifications barely grazed $p \approx .05$. The thermometer mattered.

RQ2b: defection travels along co-sponsorship ties

- Defection: in roll call v , voting against the modal vote of one's own bloc.
Exposure: the w -weighted share of i 's co-signers defecting *in the same roll call*:

$$X_{iv} = \frac{\sum_{j \neq i} w_{ij} D_{jv}}{\sum_{j \neq i} w_{ij}}, \quad \Pr(D_{iv} = 1) = \Lambda(\eta_i + \mu_v + \phi X_{iv})$$

	ϕ	p
Exposure to defectors (observed)	+11.2	$< 10^{-100}$
Expected (permutation within bloc $\times$ vote, 200 draws)	+6.0 [p95: 6.1]	< 0.005

- Half the raw effect is mechanical; **what remains is large**, travels more strongly *across* commissions, and leaves a short echo that dies within days. Carried by the *newcomer* pairs, not the old guard.

RQ3a — Texts

What makes an article survive?

The survival model: article-level, complete

- We have 1,565 *articles*, and 20.2% of them reach the draft.

$$\Pr(\text{survives}_a) = \Lambda\left(\alpha_c + \gamma_1 |\bar{\theta}_{1,S_a} - \theta_{1,(103)}| + \gamma_2 sd(\theta_{1,S_a}) + \gamma_3 |S_a| + \gamma_4^\top C_{S_a} + \gamma_5^\top H_{S_a}\right)$$

	(1) Pivotal	(2) + Network	(3) + Human capital
Coalition's distance to the $\frac{2}{3}$ pivot	-0.35 ($p = .001$)	-0.48 ($p = .009$)	-0.61 ($p = .002$)
Ideological heterogeneity $sd(\theta_1)$	+0.27 ($p = .008$)	+0.46 ($p = .001$)	+0.53 ($p < 10^{-4}$)
Coalition size	+0.20 ($p = .12$)	+0.18 ($p = .12$)	+0.15 ($p = .21$)
Mean betweenness		-0.22 ($p = .083$)	-0.23 ($p = .076$)
Mean constraint		+0.01 ($p = .97$)	+0.26 ($p = .28$)
Internal density (pairs with history)		+0.25 ($p = .024$)	+0.32 ($p = .002$)
Share of lawyers			-0.09 ($p = .58$)
Share with prior experience			-0.16 ($p = .44$)
Mean academic degree			-0.06 ($p = .67$)
AIC	1393	1384	1386

Articles win by geometry (near the pivot, ideologically wide) and by teams with internal history — not by credentials.

Survival by coalition position: the arithmetic of 103

The two-thirds rule fixed a pivot at $\theta_{1,(103)} = -0.15$. The premium for widening lives in left coalitions

RQ3b — Members

Whose success is it?

Does the context an initiative is born into matter?

- Each member's **success**: of all the article text you co-signed, how much survived into the draft? (y_i = mean textual retention of i 's articles, 0 to 1.)
- The raw fact: success is **not individual** — it clusters on the co-sponsorship network (Moran's $I = 0.44$, $p \approx 10^{-163}$). Your success looks like your co-signers' success.
- The model that takes that seriously — each member's success related to the *average success of their co-signers*, their own attributes, and their co-signers' attributes:

$$y = \rho W y + X\beta + W X\gamma + \varepsilon, \quad W = \text{row-normalized co-sponsorship network}$$

- One number, ρ , answers the title: does the company an initiative is born into matter?

The full model

	Own (β)	p	Co-signers' (γ , lag)	p
— Activity and network position				
Initiatives signed	−0.0001	.28	+0.0002	.78
Degree	+0.0004	.30	+0.0052	.31
Betweenness	−0.0000	.98	−0.0020	.40
— Ideological position				
Mean revealed vote (θ)	+0.008	.33	+0.056	.11
SD of θ	−0.018	.42	+0.026	.85
Own distance to the $\frac{2}{3}$ pivot	−0.002	.95	−0.265	.050
Ego heterophily	−0.024	.088	−0.255	.055
— Credentials and profile				
Lawyer	+0.011	.13	+0.193	.041
Prior experience	+0.019	.031	+0.170	.11
Academic degree	−0.003	.49	−0.154	.012
Female	+0.002	.78	+0.208	.075
Age	−0.0002	.53	−0.0033	.40
— Coupling				
ρ	0.891	$< 10^{-15}$	—	—

Robust across W variants: $\rho \in [0.63, 0.95]$. Own attributes predict almost nothing; the neighborhood's do — including distance to the pivot, which only matters in its “company” version.

Reading ρ : a spillover, up to identification

- This equation is not ad hoc: it is the **equilibrium of an effort game** (Battaglini et al., AJPS 2020). If my effectiveness rises with my allies' effectiveness, the unique equilibrium makes everyone's success equal their **Katz–Bonacich centrality** — and the reduced form is exactly this model.
- Under that reading — **up to an identification test currently in progress** (instrumenting the network with pre-Convention ties; the design is ready) — ρ is the **coalition-effectiveness spillover**: connected members' effectiveness spills over into yours.
- And the covariates tell you what the “context” is made of: your own distance to the pivot doesn't matter ($p = .95$) — your *co-signers'* distance does (-0.27).
The context is the coalition you stand in.
- Taken together: the evidence supports the network view of success — where you stand shapes how well you do, beyond who you are.

Takeaways

- The network **was predictable** from pre-existing traits: bloc, 2-D ideology, and — conditionally — territory. Credentials organized nothing, in any bloc.
- The bloc partition pays: territory is the right's internal glue and the system's bridge; gender crosses blocs; experience lives in the left; $gwdsp < 0$ everywhere — the structural signature of a tabula rasa.
- Positions barely move: **selection**, with one dated exception at the onset of the two-thirds regime.
- Behavior does travel: defection clusters along co-sponsorship ties at twice the mechanical rate, carried by newcomers.
- Texts win by **geometry and team history**, not credentials; and the “context” of success is the coalition itself.

Political interpretation: ongoing joint work with Jorge Fábrega. Preliminary conclusions — the analysis continues.

Thank you!

Backup

Supporting material

Backup: the bloc mixing matrix (pure closure, no profile counters)

Who co-signs with whom, net of everything else — political-bloc mixing (bipartite ERGM, MPLE + bootstrap)

Backup: the influence null, 3 windows $\times$ 7 exposure doses

Window	Exposure definition	$\hat{\lambda}$	SE	p	N
Full	Accumulated since T0	+0.007	0.004	0.119	4,355
Full	Last wave only	+0.007	0.013	0.60	463
Full	Last 2 waves	+0.003	0.009	0.72	1,504
Full	Last 3 waves	-0.002	0.007	0.76	2,447
Full	Decay $\lambda_w = 0.25/0.50/0.75$	+0.008/ +0.008/ +0.007	0.004	.051/.042/.078	4,355
Full	Falsification: future exposure	+0.010	0.004	0.030	3,329
Early ($\leq$ Mar 31)	Accumulated	+0.005	0.007	0.50	1,586
Late ($\geq$ Apr 1)	Accumulated	+0.011	0.005	0.018	2,769
Late	Falsification: future exposure	+0.010	0.004	0.004	1,742

No $\hat{\lambda}$ exceeds 0.011; the few significant late-window lags come with an equally significant falsification of the same size.

Backup: how does each sector decide? (conditional logit, same data)

	Right	Ctr-left	Left	Res. seats	Local lists
Distance in θ_1	-5.1***	-2.8**	-0.8	+0.1	-6.1***

- The complementary lens: the conditional logit conditions within each initiative (menu) and can split by the *decider's* bloc: the right almost never crosses ideological distance; the left crosses it all.
- The hybrid ERGM and the conditional logit agree on the substantive ranking — the tool changes what is visible, not what matters.
