

Networked Influence in a Tabula Rasa Legislature

Co-authorship, Ideological Dynamics, and Political Success
in the Chilean Constitutional Convention (2021–2022)

Aníbal Olivera M. · Jorge Fábrega L.

PhD(c) in Social Complexity Sciences, CICS–UDD, Chile

A natural quasi-experiment

- In an ordinary legislature, today's collaboration network is the sediment of decades: careers, committees, party discipline.
- The Chilean Constitutional Convention (Jul 2021 – Jul 2022) started from **zero relational stock**: a majority of newcomers and independents, 17 reserved indigenous seats, a body that dissolved on delivery.
- Each constitutional initiative required **8–16 sponsors**: signing = forming a visible coalition.
- Each norm needed **2/3 of the floor (103 of 154)**, so being born was cheap, but surviving was expensive.

Chile's Constitutional Convention

The pipeline

What we know about each member

- **Political**: electoral list and bloc (Right / Center-left / Left / Reserved seats / Others); district of election.
- **Profile**: age; gender; law degree; education level (HS / univ / master / PhD).
- **Prior institutional experience**: had held elective or appointed public office before the Convention (former MPs, mayors, officials) — 35 of 154 members.
- **Ideology**: two-dimensional ideal points from the first month of roll calls — measured *before* the collaboration network existed.

The seven thematic commissions

	Name (short)	Members	N lawyers	N exper.	Age	Education	Initiatives	Amd. Waves
C1	Political system	25	15	9	42.2	1.44	89	4
C2	Const. principles	18	4	4	45.8	1.28	114	3
C3	Form of the state	30	11	12	45.1	1.43	51	6
C4	Fundamental rights	30	9	4	45.9	1.03	283	5
C5	Environment	19	4	3	44.7	1.26	133	5
C6	Justice systems	17	15	3	42.6	1.65	93	6
C7	Knowledge systems	15	2	0	51.7	1.33	64	8

- Composition varies wildly across commissions — 15 of C6's 17 members are lawyers; C7 has no politically experienced member.

Ideal-point trajectories by commission membership (thin lines = delegates, thick lines = commission means)

Research questions

Formation

- **RQ1**: can the co-sponsorship network be predicted from what people *brought with them* (district, lawyer, profile)?

Behavior

- **RQ2a**: does network exposure *move* members' ideological positions?
- **RQ2b**: does voting *defection* travel along co-sponsorship ties?

Success

- **RQ3a**: what makes an *article* survive into the draft?
- **RQ3b**: does the *context* an initiative is born into matter for its authors' success?

RQ1 — Formation

Could we predict the network?

Bipartite ERGM

- Unit of analysis: the **person - initiative** signature ($y_{ia} = 1$ if member i signed initiative a).

$$\Pr(Y = y) = \frac{\exp(\theta^\top s(y))}{\kappa(\theta)}$$

$$s(y) = \left(\underbrace{\sum_{i,a} y_{ia}}_{\# \text{ edges}}, \underbrace{\sum_a \left(\max_{i: y_{ia}=1} v_i - \min_{i: y_{ia}=1} v_i \right)}_{\text{range of } v \text{ per doc}}, \text{gwb1deg}, \text{gwdsp}, \dots \right)$$

- Variables: per-document ranges of θ_1, θ_2 , age, education; the bloc contingent's own θ_1 range; gwb1degree; gwdsp.
- Seven models, one per commission.
- Estimation: MPLE as a logistic on change statistics; SEs by **initiative bootstrap** ($B = 500$).

RQ2 — People

Does the network move positions (RQ2a) or behavior (RQ2b)?

RQ2a design

- Only the **norms era** (Feb 15 – May 14, content voted under the 2/3 rule).
- Exposure has **bounded memory**: network weights decay over time, parameterized by m ($m = 1 \approx 2$ weeks, $m = 2 \approx 4$ weeks, $m = 3 \approx 6$ weeks).

$$E_{i,t}^{(m)} = \frac{\sum_{j \neq i} w_{ij,t}^{(m)} \theta_{j,t}}{\sum_{j \neq i} w_{ij,t}^{(m)}}, \quad w_{ij,t}^{(m)} = \sum_{s \leq t} \lambda_m^{t-s} \Delta w_{ij,s}$$

$$\Delta \theta_{i,t} = \alpha_i + \mu_t + \beta \theta_{i,t-1} + \lambda E_{i,t-1}^{(m)} + \lambda_{innov} \tilde{E}_{i,t+2}^{(m)} + \varepsilon_{it}$$

- $\tilde{E}_{i,t+2}^{(m)}$: decay-weighted average of *future* exposures.

The result: the referee's test at three memories

M2 (+ date FE + innovation $t+2$)	$m = 1$ (≈ 2 wks)	$m = 2$ (≈ 1 mo)	$m = 3$ (≈ 6 wks)
Lagged position $\theta_{i,t-1} (\hat{\beta})$	-0.756***	-0.756***	-0.756***
Decayed exposure $\hat{\lambda} (E_{i,t-1}^{(m)})$	0.022*** (0.006)	0.022*** (0.006)	0.021*** (0.006)
Decayed innovation $\hat{\lambda}_{innov}$	-0.008 ($p = .25$)	-0.007 ($p = .38$)	-0.005 ($p = .60$)
Wave-date fixed effects	yes	yes	yes
N (person-waves)	2,011	2,011	2,011
R^2 within	0.370	0.370	0.369

- The lag stands at ~ 0.022 — closing $\sim 2\%$ of the distance to the recent neighborhood per wave — and the **strictly future innovation predicts nothing**, at every memory.
- Honest label: an **influence component** that survives every test this panel supports; latent homophily cannot be excluded by design.

RQ2b: defection — the design

- When someone breaks ranks: alone, or together with the people they wrote initiatives with?

$$X_{iv} = \frac{\sum_{j \neq i} w_{ij} D_{jv}}{\sum_{j \neq i} w_{ij}}, \quad \Pr(D_{iv} = 1) = \Lambda(\eta_i + \mu_{b(i),v} + \phi X_{iv} + \gamma \text{margin}_{iv})$$

- η_i absorbs the born rebels; $\mu_{b(i),v}$ absorbs “this vote split this bloc”.
- ϕ is the **parameter of interest**: do I defect more when my people defect?
- margin_{iv} : distance to one’s own bloc’s median position.

RQ2b: the result (final model)

	Estimate	(SE)
Exposure to defecting co-signers (ϕ)	8.75***	(0.61)
Marginality in own bloc (γ)	1.09***	(0.09)
Fixed effects	person + bloc $\times$ vote	
N (member-votes)	186,988	

- Same bloc, same vote, same pressure: the members whose co-signers defect, **defect far more**.
- Marginality predicts defection strongly — the bloc's outsider breaks ranks — but takes *nothing* from ϕ : two independent channels.
- Carried by **newcomers at both ends** of the tie: novice receivers ($\phi = 12.2$ vs 9.5) and novice senders alike.

Validation: shuffling *who* defected within each bloc $\times$ vote (200 draws) puts the mechanics-only ϕ at 6.0; the raw two-way-FE number is 11.2. Full ladder in the paper.

RQ3a — Texts

What makes an article survive?

The survival model: article-level, complete

- We have 1,565 *articles*, and 20.2% of them reach the draft.

$$\Pr(\text{survives}_a) = \Lambda\left(\alpha_c + \gamma_1 |\bar{\theta}_{1,S_a} - \theta_{1,(103)}| + \gamma_2 sd(\theta_{1,S_a}) + \gamma_3 |S_a| + \gamma_4^\top C_{S_a} + \gamma_5^\top H_{S_a}\right)$$

	(1) Pivotal	(2) + Network	(3) + Human capital
Coalition's distance to the $\frac{2}{3}$ pivot	-0.35 ($p = .001$)	-0.48 ($p = .009$)	-0.61 ($p = .002$)
Ideological heterogeneity $sd(\theta_1)$	+0.27 ($p = .008$)	+0.46 ($p = .001$)	+0.53 ($p < 10^{-4}$)
Coalition size	+0.20 ($p = .12$)	+0.18 ($p = .12$)	+0.15 ($p = .21$)
Mean betweenness		-0.22 ($p = .083$)	-0.23 ($p = .076$)
Mean constraint		+0.01 ($p = .97$)	+0.26 ($p = .28$)
Internal density (pairs with history)		+0.25 ($p = .024$)	+0.32 ($p = .002$)
Share of lawyers			-0.09 ($p = .58$)
Share with prior experience			-0.16 ($p = .44$)
Mean academic degree			-0.06 ($p = .67$)
AIC	1393	1384	1386

Articles win by geometry (near the pivot, ideologically wide) and by teams with internal history — not by credentials.

Survival by coalition position: the arithmetic of 103

The two-thirds rule fixed a pivot at $\theta_{1,(103)} = -0.15$. The premium for widening lives in left coalitions 24

RQ3b — Members

Whose success is it?

Does the context an initiative is born into matter?

- **Success**: of all the article text you co-signed, how much survived into the draft? (y_i = mean textual retention of i 's articles, 0 to 1.)
- Success is **not individual**: it clusters on the co-sponsorship network (Moran's $I = 0.44$, $p \approx 10^{-163}$). Your success looks like your co-signers' success.
- To test whether the company an initiative is born into matters, we relate each member's success to the *average success of their co-signers*:

$$y = \rho W y + X\beta + W X\gamma + \varepsilon,$$

where W is the row-normalized co-sponsorship network.

- One coefficient, ρ , answers whether that company matters.

The full model

	Own (β)	p	Co-signers' (γ , lag)	p
— Activity and network position				
Initiatives signed	−0.0001	.28	+0.0002	.78
Degree	+0.0004	.30	+0.0052	.31
Betweenness	−0.0000	.98	−0.0020	.40
— Ideological position				
Mean revealed vote (θ)	+0.008	.33	+0.056	.11
SD of θ	−0.018	.42	+0.026	.85
Own distance to the $\frac{2}{3}$ pivot	−0.002	.95	−0.265	.050
Ego heterophily	−0.024	.088	−0.255	.055
— Credentials and profile				
Lawyer	+0.011	.13	+0.193	.041
Prior experience	+0.019	.031	+0.170	.11
Academic degree	−0.003	.49	−0.154	.012
Female	+0.002	.78	+0.208	.075
Age	−0.0002	.53	−0.0033	.40
— Coupling				
ρ	0.891	<.001	—	—

Reading ρ : a spillover, up to identification

- The term ρWy is the *equilibrium of an effort game*, and tell us the **coalition-effectiveness spillover***: connected members' effectiveness spills over into yours (Battaglini et al., AJPS 2020).
- And the covariates tell you what the “context” is made of: your own distance to the pivot doesn't matter ($p = .95$), your *co-signers*' distance does (-0.27). **The context is the coalition you stand in.**
- Taken together: the evidence supports the network view of success — where you stand shapes how well you do, beyond who you are.

* Up to an identification test currently in progress.

Conclusions

- The network **was predictable** from what people brought with them: political bloc and — conditionally — shared district. Credentials organized nothing, in any bloc.
- Territory is the right's internal glue and the system's bridge; gender crosses blocs; and $gwdsp < 0$ everywhere: coalitions re-form with fresh pairs — the **structural signature of a tabula rasa**.
- In the norms era, positions **drift toward the recent neighborhood** ($\sim 2\%$ of the distance per wave), and the strictly-future placebo shows nothing: an influence component, not just selection.
- Defection **travels along co-sponsorship ties** — same bloc, same vote, same pressure — carried by newcomers at both ends.
- Articles win by **geometry and team history**, not credentials; and for the authors, **the context is the coalition**: success is a coalition good.

Thank you!

Backup

Supporting material

Backup: the bloc mixing matrix (pure closure, no profile counters)

Who co-signs with whom, net of everything else — political-bloc mixing (bipartite ERGM, MPLE + bootstrap)

Backup: the influence null, 3 windows $\times$ 7 exposure doses

Window	Exposure definition	$\hat{\lambda}$	SE	p	N
Full	Accumulated since T0	+0.007	0.004	0.119	4,355
Full	Last wave only	+0.007	0.013	0.60	463
Full	Last 2 waves	+0.003	0.009	0.72	1,504
Full	Last 3 waves	-0.002	0.007	0.76	2,447
Full	Decay $\lambda_w = 0.25/0.50/0.75$	+0.008/ +0.008/ +0.007	0.004	.051/.042/.078	4,355
Full	Falsification: future exposure	+0.010	0.004	0.030	3,329
Early ($\leq$ Mar 31)	Accumulated	+0.005	0.007	0.50	1,586
Late ($\geq$ Apr 1)	Accumulated	+0.011	0.005	0.018	2,769
Late	Falsification: future exposure	+0.010	0.004	0.004	1,742

No $\hat{\lambda}$ exceeds 0.011; the few significant late-window lags come with an equally significant falsification of the same size.

Backup: how does each sector decide? (conditional logit, same data)

	Right	Ctr-left	Left	Res. seats	Others
Distance in θ_1	-5.1***	-2.8**	-0.8	+0.1	-6.1***

- The complementary lens: the conditional logit conditions within each initiative (menu) and can split by the *decider's* bloc: the right almost never crosses ideological distance; the left crosses it all.
- The hybrid ERGM and the conditional logit agree on the substantive ranking — the tool changes what is visible, not what matters.
